

COST Action E48 “The Limits of Paper Recycling”

**Plenary Meeting
Zagreb – October 26th, 2006**

Removing Stickies by Screening Some results obtained at CTP

François JULIEN SAINT AMAND

Background

**EU Project ScreenClean (2002-2004) aiming at optimising the removal of primary PSA stickies in deinking lines:
CTP program focused on screening & cleaning**

- **BAT to remove macro-stickies: slot screening**
- **Fundamental aspects studied in cooperation with LEGI/CNRS Grenoble and ITM/TU Czestochowa**
- **Screening tests on pilot / industrial scale: cooperation with equipment suppliers: Kadant-Lamort and AFT**
- **Optimisation of screening systems with the help of simulation tools developed at CTP**

**On-going project focused on HC screening of PSA stickies:
ScreenStic (2005-2006)**

- **Stickies fragmentation and optimisation of pulp consistency**

How did we proceed ?

Improve understanding of screening hydrodynamics

- Typical pressure pulse with foils: short-time phenomena
- CFD simulation with LEGI: exit layer thickness ($\propto V_s/V_t$) determines fibre passage probability through slots, i.e. fibres pass easier at high V_s

Study stickies removal

- Rejected by screen plate profiles ? → Pilot studies
- Soft PSA stickies are extruded through slots ? → Lab studies and numerical simulation at ITM

Lab studies Stickies extrusion: Steady pressure

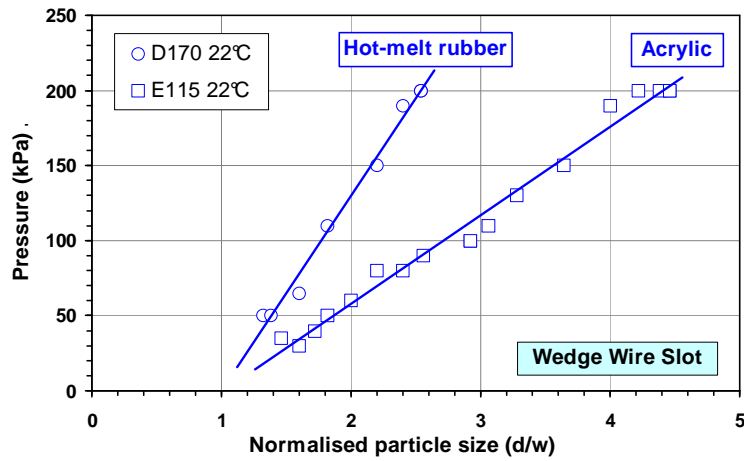

Visualisation of PSA stickies extrusion

- Single slot lab screen: first tests done under steady pressure
- Parameters studied: stickies size, pressure, °C, pH; type of slots

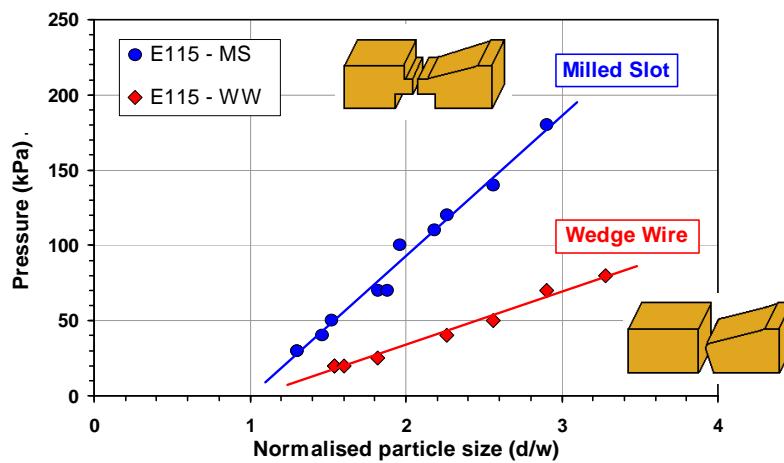

Stickies extrusion: Steady pressure Effect of adhesive material

- Water-based acrylic adhesive E115 is extruded through the slot at lower pressure than hot-melt rubber adhesive D170. E115 is softer.

Stickies extrusion: Steady pressure Effect of slot inlet design

- Less pressure with WW slots, i.e. larger adhesive particles (E 115) are extruded through WW slots compared to milled slots, at given pressure.

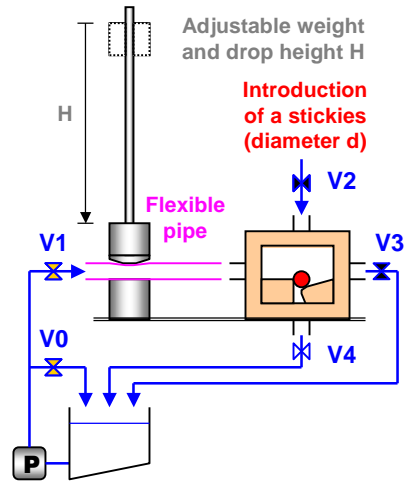

Lab studies Stickies extrusion: Unsteady pressure

Tests at unsteady pressure

- Pressure pulse: 15 ms

7/19/04 1:38:52 PM 1700.1178.9[mc] CAM profil_1
(1017 Hz)

Result

- $d/w < 1.2$: stickies pass
- Since larger stickies can pass: several rotor revolutions

Screening Stickies – FJSA (CTP) – 7

COST E-48 Plenary meeting – Zagreb 26/10/2006

WW - d/w 1.3 - 80kPa - NaOH - 50°C

Stickies slot penetration ratio
• Defined by $h.w / \pi.(d/2)^2$

WW - d/w 3.5 - 150kPa - NaOH - 50°C

WW - d/w 5.5 - 110kPa - NaOH - 50°C

WW - d/w 5.0 - 200kPa - NaOH - 50°C

Pilot stickies screening tests Experimental equipment and methods

Preparation of the pulp and adhesive particles

- Adhesive labels stuck onto fresh newspaper to produce dark particles
- LC lab. pulper with 2% adhesive, 50% newspapers / 50% magazines
- 30 min. pulping at 55°C with standard INGEDE deinking chemistry
- Mixture of the adhesive containing pulp with bleached pulp: contrast

Experimental equipment and methods

- Industrial sized "slice screen" (500 mm screen cylinder diameter)
- Tests at 50% reject flow rate to simulate a slice of industrial screen
- Characterisation of the behaviour of probability particles (fibres, stickies) by their **passage ratio: C_d / C_u** (probability screening theory)

Pilot stickies screening tests Optimisation of screen plate design

Effect of slot inlet design (milled vs. WW)

- Cleaner accept pulp with milled slots
→ lower stickies passage
- Higher reject thickening with milled slots
→ lower fibre passage
- At given reject rate: only slightly better efficiency (& lower capacity) with milled versus wedge wire slots

Effect of profile height and angle (comparison of WW slots)

- Slot width: 0.15 mm
- Profile height: 0.6 - 1.2 mm
- Wire width: 2.6 - 3.2 mm
- Profile angle: 13 - 25°

Optimisation of screen plate design

Results with acrylic PSA stickies (0.3-1mm²) – $R_v = 50\%$

- Best screening selectivity with low profiles (0.6 mm)

- Higher cleanliness efficiency at reduced slot velocity (V_s)

Results: effect of screen plate design

Simplified simulation using plug-flow model – $R_w = 1\%$

- Best screening system efficiency with low profiles and low V_s

- Same conclusion with advanced screening system simulation

Synthesis on LC stickies screening

Extrusion of stickies through slots

- Both experimental and numerical studies showed more extrusion with:
 - softer adhesives (soaked acrylic adhesive at high temperature)
 - wedge wire slots compared to milled slots
- High stickies extrusion time (\gg P+)
 - **Multi-step extrusion process**

Optimisation of screen plate design

- The first pilot tests confirmed that less extrusion improved efficiency:
 - better results at low temperature and with a milled screen plate
- Much higher efficiency gains were obtained with optimised contours:
 - 1) low contours (0.6 mm height)
 - 2) low angle (20° and less)
- **Particle slip over contours** (contacts) should have more impact on the removal of stickies than the extrusion phenomena, at least at low consistency

Synthesis on LC stickies screening and perspectives

Optimisation of screen operating parameters

- **Slot velocity**
 - relevant parameter: effective slot velocity during screening phase
 - higher efficiency at reduced slot velocity, but
 - higher costs (lower screening capacity and more reject thickening)
- **Consistency**
 - possible to increase long fibre consistency, i.e. R14+R28 McNett fractions, up to about 1% without hindering the screening process
 - opportunity to optimise screening costs (equipment and energy)

Optimisation of stickies removal

- **Keep them large !**
 - optimisation of pulping to produce large stickies in order to remove them as early as possible in the deinking / recycling line
 - minimize stickies fragmentation at the first screening steps
 - eco-designed adhesive products
